

# Corrosion, Batteries, and Design Evidence

Student Worksheet | g10\_u06\_w24

**I can:** use redox and supplied mass-loss data to compare bounded corrosion-prevention models.

**Supplied models:** In a bare-iron corrosion card,  $\text{Fe(s)} \rightarrow \text{Fe}^{2+}(\text{aq}) + 2\text{e}^-$  is anodic oxidation and a supplied oxygen-reduction site is cathodic. In a Zn–Fe contact card, Zn is stated to be the anode:  $\text{Zn(s)} \rightarrow \text{Zn}^{2+}(\text{aq}) + 2\text{e}^-$ , so electrons travel  $\text{Zn} \rightarrow \text{Fe}$  through the contact. A battery uses deliberately separated redox pathways to deliver external electron flow; corrosion can create unintended local galvanic regions. Use only data cards/simulations—no metal, electrolyte, battery, or device work.

| card (10 d, same environment) | Fe loss (g) | Zn loss (g) | stated feature                    |
|-------------------------------|-------------|-------------|-----------------------------------|
| A                             | 0.40        | —           | bare Fe                           |
| B                             | 0.02        | —           | intact coating on Fe              |
| C                             | 0.30        | —           | scratched coating on Fe           |
| D                             | 0.05        | 0.32        | scratched coating + Zn–Fe contact |

1. In the bare-iron model, identify the oxidation half-reaction.

---

---

2. In that half-reaction, are electrons reactants or products? What does that show?

---

---

3. Which electrode role is assigned to an iron site where that oxidation occurs?

---

---

4. What process occurs at the supplied oxygen-reduction site?

---

---

5. Compare a battery model with a corrosion model: what redox feature can they share, and what important purpose difference remains?

---

---

6. In the supplied Zn–Fe contact card, which metal is the anode?

---

---

7. Which metal is the cathodic/protected surface in that stated model?

---

---

8. State the electron-flow direction through the Zn–Fe contact.

---

---

9. Which metal should lose mass through anodic oxidation in the supplied contact model?

---

---

10. Calculate the Fe mass-loss rate for card A in g/day.

---

---

11. Calculate the Fe mass-loss rate for card C in g/day.

---

---

12. Calculate the Fe mass-loss rate for card D in g/day.

---

---

13. Relative to card C, calculate the percent decrease in Fe mass-loss rate for card D.

---

---

14. Calculate the Zn mass-loss rate for card D in g/day.

---

---

15. What bounded inference does cards C and D support about the stated Zn–Fe contact model?

---

---

16. Explain how an intact coating can reduce exposure in a corrosion model.

---

---

17. Why does the scratched-coating card prevent a claim that coating always eliminates corrosion?

---

---

18. Critique: “If Zn loses mass, the prevention design has failed.” Use the supplied galvanic convention.

---

---

19. Choose one prevention model to test further for the same supplied environment. Cite one benefit and one tradeoff, without making a medical, environmental, or device-design claim.

---

---

20. Write a cautious CER statement using one redox convention and one data calculation. Include the data/simulation safety boundary and one limitation on generalization.

---

---

---

---

---

---

---
